FREQUENCY-DEPENDENT IMPEDANCE SYNTHESIS FOR DSL INTERFACE CIRCUITS

BACKGROUND OF THE INVENTION

Field of the Invention

5 The present invention relates to the field of telecommunications and, more specifically, to telecommunication electronics.

Description of the Related Art

10 Fig. 1 illustrates a telephone service arrangement between a subscriber **10** (e.g., residential or commercial telephone customer) and a service provider **12** that exchanges data with a telephone company central office (TCCO) **14** to provide telephone service to subscriber **10**. There are many telecommunication standards that service provider **12** should comply with to insure compatibility between telecommunication devices at subscriber **10** and service provider **12**.

15 One of the standards with which service provider **12** should comply is the Telcordia Standard TR-NWT-000057 (referred to herein as the "Telcordia Standard"), which specifies the impedance level a telecommunication device at subscriber **10** should encounter when a connection is established with service provider **12**. According to the Telcordia Standard, this impedance level is 900 ohms (Ω) + 2.16 microfarads (μF) as viewed by subscriber **10** between the tip line **16** and ring line **18** (referred to herein as the tip/ring lines **20**). Telecommunication devices for use at subscriber **10** are designed based on the impedance level set forth in the Telcordia Standard and, therefore, if the impedance of tip/ring lines **20** deviates from this standard, telephone service may be affected adversely.

20 In traditional audio only telephone service arrangements (i.e., plain old telephone service, "POTS"), a subscriber line interface circuit (SLIC) **22** and a coder/decoder (CODEC) **24** generate a suitable impedance level between tip/ring lines **20**. CODEC **24** develops a signal based on an output from SLIC **22** at ports VTX and VRTX that reflects current sensed by SLIC **22** at protected tip (PT) port and protected ring (PR) port. The developed signal can be fed back to tip/ring lines **20** via CODEC output ports VRN and VRP and further via SLIC ports PT and PR to synthesize an impedance that complies with the Telcordia Standard, i.e., 900 Ω + 2.16 μF . In a typical arrangement, SLIC **22** receives the signal from CODEC **24** through a non-inverting receive AC signal input (RCVP) and an inverting receive AC signal input (RCVN).

25 Recently, asynchronous digital subscriber line (ADSL) has become a common standard for transferring data at a very high rate between subscriber **10** and TCCO **14**. ADSL service is provided over the same tip/ring lines **20** as POTS. The ADSL signals are transmitted in a frequency band above about 25 kHz, whereas traditional POTS signals are transmitted in a frequency band below about 4 kHz.

30 Fig. 2 illustrates an interface circuit **200** within service provider **12** of Fig. 1 for separating ADSL and POTS signals received from subscriber **10** for transmission to TCCO **14**, and combining ADSL and POTS

signals received from TCCO 14 for transmission to subscriber 10. Interface circuit 200 of Fig. 2 adds a transformer 26, which contains a blocking capacitor 28, to the service arrangement of Fig. 1. Ideally, transformer 26 exhibits low impedance to signals in the ADSL band. Blocking capacitor 28 is selected to prevent low frequency signals (e.g., signals in the POTS band) from passing through transformer 26, thereby creating a “pure” ADSL signal for processing by ADSL circuitry 30 at service provider 12. In addition, a low-pass filter (LPF) 32, which contains a coupled inductor 34 and a capacitor 36, is added to filter out signals in the ADSL band, thereby creating a “pure” POTS signal for processing by SLIC 22 and CODEC 24. A first resistor 38 is coupled between the PT port of SLIC 22 and LPF 32 and a second resistor 40 is coupled between the PR port of SLIC 22 and LPF 32 to provide protection for SLIC 22. Also, a first protection circuit 42 and a second protection circuit 44 are coupled between SLIC 22 and tip/ring lines 20 to protect SLIC 22 from voltage spikes created by coupled inductor 34 of LPF 32.

A problem that arises when transformer 26 containing blocking capacitor 28 is inserted into the traditional POTS circuitry is that, at higher frequencies of the POTS band, e.g., above about 2 kHz, blocking capacitor 28 begins to pass AC current. Because current begins to flow through blocking capacitor 28 at these frequencies, the impedance of tip/ring lines 20 is essentially the impedance developed by CODEC 24 and SLIC 22 in parallel with the impedance of blocking capacitor 28. (The impedance through the windings of transformer 26 is essentially zero at these frequencies.) This reduces the impedance of tip/ring lines 20 at these higher POTS band frequencies, thereby adversely affecting the quality of the POTS.

Accordingly, methods and/or circuits are needed to compensate for the blocking capacitor’s effect on impedance for signals having frequencies in the POTS band, while not adversely affecting the impedance for signals having frequencies in the ADSL band.

SUMMARY OF THE INVENTION

The present invention provides an impedance warping circuit (IWC) and technique for compensating the effect of a blocking capacitor within a transformer of an interface circuit for passing POTS band and ADSL band signals, on signals having frequencies in the POTS band. The IWC does not significantly affect the performance of the interface circuit in the ADSL band. The IWC synthesizes impedance to compensate the frequency-dependent deviation in the termination impedance across the tip/ring lines. The resulting termination impedance conforms to, e.g., the Telcordia Standard of $900\ \Omega + 2.16\ \mu\text{F}$ throughout the entire POTS band. The IWC can be implemented using very few circuit components, such as two operational amplifiers.

According to one embodiment, the present invention is an interface circuit for interfacing between a pair of subscriber tip/ring lines and a central office of a telecommunications network, the interface circuit comprising: (a) filter circuitry configured to separate low-frequency and high-frequency signals appearing on the tip/ring lines, wherein the filter circuitry comprises a blocking capacitor that affects the low-frequency

impedance of the tip/ring lines; (b) high-frequency interface circuitry configured to process the high-frequency signals; and (c) low-frequency interface circuitry configured to process the low-frequency signals, wherein the low-frequency interface circuitry comprises: (1) a subscriber line interface circuit (SLIC) configured between the tip and ring lines; (2) a coder/decoder (CODEC) configured to encode and decode the low-frequency signals; and (3) an IWC configured between the SLIC and the CODEC, wherein the IWC tends to compensate for the effect of the blocking capacitor on the low-frequency impedance between the tip/ring lines.

According to another embodiment, the present invention is an IWC for an interface circuit for interfacing between a pair of subscriber tip/ring lines and a central office of a telecommunications network, the interface circuit comprising: (a) filter circuitry configured to separate low-frequency and high-frequency signals appearing on the tip/ring lines, wherein the filter circuitry comprises a blocking capacitor that affects the low-frequency impedance of the tip/ring lines; (b) high-frequency interface circuitry configured to process the high-frequency signals; and (c) low-frequency interface circuitry configured to process the low-frequency signals, wherein the low-frequency interface circuitry comprises: (1) a subscriber line interface circuit (SLIC) configured between the tip and ring lines; (2) a coder/decoder (CODEC) configured to encode and decode the low-frequency signals; and (3) the IWC configured between the SLIC and the CODEC, wherein the IWC tends to compensate for the effect of the blocking capacitor on the low-frequency impedance between the tip/ring lines..

BRIEF DESCRIPTION OF THE DRAWINGS

Other aspects, features, and advantages of the present invention will become more fully apparent from the following detailed description, the appended claims, and the accompanying drawings in which:

Fig. 1 is a schematic block diagram of a prior art telephone service arrangement;

Fig. 2 is a schematic block diagram of an interface circuit for passing POTS band and ADSL band signals;

Fig. 3 is a schematic block diagram of an interface circuit for passing POTS band and ADSL band signals having an impedance warping circuit according to one embodiment of the present invention;

Fig. 4 is a schematic diagram of the impedance warping circuit that can be used in the interface circuit of Fig. 3 according to one embodiment of the present invention;

Fig. 5 is a schematic block diagram of the impedance warping circuit that can be used in the interface circuit of Fig. 3 according to another embodiment of the present invention; and

Fig. 6 is a graph illustrating a typical difference in two-wire return loss for interface circuits with and without the impedance warping circuit of Fig. 4.

DETAILED DESCRIPTION

Reference herein to “one embodiment” or “an embodiment” means that a particular feature, structure, or characteristic described in connection with the embodiment can be included in at least one embodiment of the invention. The appearances of the phrase “in one embodiment” in various places in the specification are not necessarily all referring to the same embodiment, nor are separate or alternative embodiments mutually exclusive of other embodiments. The description herein is largely based on a particular interface circuit for passing POTS band and ADSL band signals for the Telcordia Standard. Those skilled in the art can appreciate that the description can be equally applied to other interface circuits and/or other standards.

Fig. 3 shows a schematic block diagram of an interface circuit **300** for use at service provider **12** of Fig. 1 according to one embodiment of the present invention. Interface circuit **300** is similar to interface circuit **200** of Fig. 2. However, in its impedance generating circuitry, interface circuit **300** incorporates an impedance warping circuit (IWC) **302** connected to SLIC **22** and CODEC **24**. CODEC **24** and IWC **302** are configured to synthesize impedance on tip/ring lines **20** complying with the Telcordia Standard. SLIC **22** is configured to interface CODEC **24** and IWC **302** with tip/ring lines **20**.

During operation of interface circuit **300**, transformer **26** passes signals having frequencies that are above a predetermined frequency to ADSL circuitry **30** and prevents signals having frequencies below this predetermined frequency from passing to ADSL circuitry **30**. Transformer **26** includes blocking capacitor **28**, which acts as an open circuit for signals having frequencies below the predetermined frequency, thereby preventing these signals from passing through transformer **26** to ADSL circuitry **30**. At frequencies near the predetermined frequency, however, blocking capacitor **28** begins to pass current, thereby reducing the impedance between tip/ring lines **20**.

In one embodiment, blocking capacitor **28** is selected to allow transformer **26** to pass signals having a frequency above about 4 kHz for processing by ADSL circuitry **30**. Since ADSL signals have frequencies above about 25 kHz and POTS signals have frequencies below about 4 kHz, transformer **26** in this embodiment substantially allows only the ADSL signals to pass through to ADSL circuitry **30**. However, blocking capacitor **28** will begin to pass current in the upper POTS frequency band at frequencies near 4 kHz, e.g., above about 2 kHz for a 33-nF blocking capacitor.

Low-pass filter (LPF) **32** passes signals having frequencies that are below a predetermined frequency and prevents signals having frequencies above this predetermined frequency from passing. In the illustrated embodiment, LPF **32** is coupled between tip line **16** and ring line **18**. In addition, LPF **32** is coupled to CODEC **24** and IWC **302** through SLIC **22**. In one embodiment, LPF **32** includes a coupled inductor **34** and a capacitor **36**. Coupled inductor **34** and capacitor **36** are selected in a known manner to block signals having frequencies above the predetermined frequency and pass signals having frequencies below that frequency. In one embodiment, signals in the ADSL frequency band, e.g., above about 25 kHz, are blocked, while signals in the POTS frequency band, e.g., below about 4 kHz, are allowed to pass for processing by CODEC **24**,

IWC 302, and SLIC 22.

SLIC 22 is a subscriber line interface circuit. In the embodiment illustrated in Fig. 3, SLIC 22 couples CODEC 24 and IWC 302 to tip/ring lines 20 through LPF 32. Applying a differential current to ports PT and PR of SLIC 22 results in a single-ended signal proportional to the differential current being output at port VTX. A signal applied on either the RCVN or RCVP ports of SLIC 22 results in a differential voltage signal at ports PT and PR that can be used to generate a differential voltage between tip/ring lines 20.

In one embodiment, SLIC 22 senses the current of tip/ring lines 20 through the PT and PR ports coupled to tip/ring lines 20 through a pair of resistors 38 and 40, protection circuits 42 and 44, and LPF 32. Port VTX of SLIC 22 is coupled to CODEC 24 and IWC 302 for passing an output signal proportional to the difference in current between tip/ring lines 20. Port VRTX of SLIC 22 is also coupled to CODEC 24 and IWC 302 for providing a voltage reference (preferably one half of the power supply voltage) for circuitry components within CODEC 24 and IWC 302. Ports RCVN and RCVP of SLIC 22 are coupled to the output of IWC 302 to receive signals generated by IWC 302. SLIC 22 may be a L7585F Full-Feature, Low-Power SLIC and Switch available through Lucent Technologies, Inc. of Murray Hill, NJ, USA. CODEC 24 may be a programmable CODEC, such as the T8531/T8532 model CODEC, available from Agere Systems, Inc. of Allentown, PA, USA.

In a conventional configuration, such as one shown in Fig. 1, CODEC 24 processes information received from tip/ring lines 20 via SLIC 22 and generates an impedance voltage level at ports VRN and VRP that can be used to synthesize the impedance between tip/ring lines 20. SLIC 22 then generates a differential voltage at ports PT and PR based on the impedance voltage from CODEC 24, thereby synthesizing an impedance on tip/ring lines 20 through LPF 32. However, with the addition of transformer 26 and ADSL circuitry 30 as illustrated in Fig. 2, the synthesized impedance of SLIC 22 and blocking capacitor 28 become coupled to tip/ring lines 20 effectively in parallel. In the upper POTS frequency band, the frequency-dependent impedance of blocking capacitor 28 may cause the combined impedance to deviate from the Telcordia Standard. Referring back to Fig. 3, IWC 302 present between CODEC 24 and SLIC 22 of interface circuit 300 serves to alter the impedance voltage generated by CODEC 24 in such a way that the synthesized impedance taken in parallel with blocking capacitor 28 complies with the Telcordia Standard.

Fig. 4 shows a schematic diagram of IWC 302 according to one embodiment of the present invention. IWC 302 comprises amplifiers 402 and 404 and an optional output filter 406. Amplifier 402 converts the differential output of CODEC 24 into a first single-ended signal coupled to port RCVN of SLIC 22 via optional output filter 406. Amplifier 404 converts the differential output of SLIC 22 into a second single-ended signal that is coupled back to SLIC 22 at port RCVP. The first and second single-ended output signals of amplifiers 402 and 404 are used to generate a differential output signal of IWC 302 applied to SLIC 22 at ports RCVN and RCVP.

In one embodiment, amplifier 402 comprises a first operational amplifier 412 configured as an

inverter using resistors R1, R2, R2A, and R3. The non-inverting and inverting inputs of amplifier **412** are connected to port VRN of CODEC **24** via resistor R2 and port VRP of CODEC **24** via resistor R2A, respectively. The non-inverting input of amplifier **412** is also connected to port VRTX of SLIC **22** via resistor R1. Resistor R3 connects the inverting input and the output of amplifier **412**. Amplifier **404** comprises a second operational amplifier **414** configured as a frequency-dependent inverter. Amplifier **414** has resistor R7 in parallel with compensating capacitor C2 connected between its output and the inverting input. The non-inverting input of amplifier **414** is connected to port VRTX of SLIC **22**. The inverting input of amplifier **414** is connected to port VTX of SLIC **22** via resistor R6. Optional output filter **406** comprises (i) resistor R4 connected between the output of amplifier **412** and port RCVN of SLIC **22** and (ii) resistor R5 and capacitor C1 in series connected between ports RCVN and VRTX of SLIC **22**. Optional output filter **406** is preferably used with Sharc CODEC available from Agere Systems, Inc. of Allentown, PA, USA.

Fig. 5 shows a schematic diagram of IWC **302** according to another embodiment of the present invention. As shown in Fig. 5, IWC **302** comprises amplifiers **402** and **504**. Amplifier **402** and its operation have already been described in the context of Fig. 4. However, in the embodiment of Fig. 5, the polarity of connections of amplifier **402** to CODEC **24** and SLIC **22** is different from that of Fig. 4. In the embodiment of Fig. 5, the non-inverting and inverting inputs of amplifier **412** are now connected to port VRP of CODEC **24** via resistor R2 and port VRN of CODEC **24** via resistor R2A, respectively. Also, the single-ended output of amplifier **412** is now coupled to port RCVP of SLIC **22** instead of port RCVN as shown in Fig. 4. Similar to amplifier **404** of Fig. 4, amplifier **504** converts the differential output of SLIC **22** into a single-ended output signal. However, the single-ended output signal of amplifier **504** is coupled to SLIC **22** at port RCVN instead of port RCVP for amplifier **404**. The single-ended output signals of amplifiers **402** and **504** are used to generate a differential output signal of IWC **302** applied to SLIC **22** at ports RCVP and RCVN.

In one embodiment, amplifier **504** comprises an operational amplifier **514** configured as a frequency-dependent non-inverting buffer. Amplifier **514** has resistor R8 connected between its output and the inverting input. The inverting input of amplifier **514** is connected to port VRTX of SLIC **22** via resistor R9. The non-inverting input of amplifier **514** is connected to port VTX of SLIC **22** via resistor R6A. The non-inverting input of amplifier **514** is also connected to port VRTX of SLIC **22** via resistor R7A and compensating capacitor C2A configured in parallel with each other.

Referring again to Fig. 4, the gain K_1 of amplifier **402** is set by resistors R2A and R3 and, therefore, is not frequency-dependent. In contrast, the gain K_2 of amplifier **404** is frequency-dependent and can be expressed by Eqn. (1) as follows:

$$K_2(\omega) = \frac{R_7}{R_6} \frac{1}{(1 + i\omega C_2 R_7)} \quad (1)$$

where R_6 , R_7 , and C_2 are resistances and capacitance of resistors R6 and R7 and compensating capacitor C2, respectively; $\omega = 2\pi f$; and f is frequency. As can be seen from Eqn. (1), K_2 decreases as frequency of the

applied signal, e.g., signal on tip/ring lines **20**, increases. Because the output signals of amplifiers **402** and **404** are used differentially, the differential output signal of IWC **302** will increase with frequency by virtue of subtracting the decreasing frequency-dependent output signal of amplifier **404** from the frequency-independent output signal of amplifier **404**.

The transfer function $T(\omega)$ of the combination of CODEC **24** and IWC **302** shown in Fig. 4 can be calculated as follows:

$$T(\omega) = K_0 K_1 - K_2(\omega) \quad (2)$$

where K_0 is the gain of CODEC **24**. Combining Equations (1) and (2) and substituting K_3 for R_7/R_6 and ω_0^{-1} for $C_2 R_7$, respectively, one arrives at the following expression for the transfer function:

$$T(\omega) = K_0 K_1 - \frac{K_3}{1 + i\omega\omega_0^{-1}} \quad (3)$$

At relatively low frequencies, where

$$\omega/\omega_0 \ll 1 \quad (4)$$

Eqn. (3) can be expanded into the following expression:

$$T(\omega) \approx (K_0 K_1 - K_3) + iK_3\omega\omega_0^{-1} \quad (5)$$

Eqn. (5) describes the frequency-dependent transfer function of the combination of CODEC **24** and IWC **302** of interface circuit **300**.

To illustrate how, using the transfer function expressed by Eqn. (5), the combination of CODEC **24** and IWC **302** can be configured to compensate the effect of blocking capacitor **28** on the impedance on tip/ring lines **20**, let us consider the following. Suppose that one has an impedance Z_l in parallel with a capacitor C_{28} and needs the combined impedance of the two to be $Z_0 = 900 \, \Omega + 2.16 \, \mu\text{F}$. Then Z_0 can be expressed as:

$$\frac{1}{Z_0} = \frac{1}{Z_l} + i\omega C_{28} \quad (6)$$

and Z_l can be calculated as:

$$Z_l = \frac{Z_0}{(1 - i\omega C_{28} Z_0)} \quad (7)$$

If

$$|\omega C_{28} Z_0| \ll 1 \quad (8)$$

e.g., relatively low frequencies and/or relatively small capacitor C_{28} , then Eqn. (7) can be expanded as follows:

$$Z_l \approx Z_0 (1 + i\omega C_{28} Z_0) \quad (9)$$

Comparing Equations (5) and (9), one finds that they define analogous transfer functions, thereby enabling CODEC **24** and IWC **302** to compensate for the effect of blocking capacitor **28** and synthesize an impedance

on tip/ring lines **20** that will comply with the Telcordia Standard essentially throughout the entire POTS-band frequency range.

In one embodiment of the present invention, nominal values of resistors R2A, R3, R6, R7 and capacitors C2 and C28 are chosen to hold Equations (5) and (9) to within approximately 10% of Equations (3) and (7), respectively, and to within approximately 10 % of each other at frequencies in the upper POTS band, e.g., around 2 to 4 kHz. In a preferred embodiment of IWC **302**, resistors R1, R2, R2A, R3, R6, R7 are about 10 k Ω each and compensating capacitor C2 is about 3.3 nF. These values are preferably used with CODEC **24** whose gain K_0 is set at about 2. In another embodiment of IWC **302**, resistors R4 and R5 are about 10 and 5.5 k Ω , respectively, and capacitor C1 is about 330 pF.

Fig. 6 illustrates a typical difference in two-wire return loss observed for an interface circuit without an IWC (e.g., interface circuit **200** of Fig. 2) and an interface circuit with an IWC (e.g., interface circuit **300** of Fig. 3). In an ideal situation (not shown), when an interface circuit is perfectly matched to the tip/ring lines, the two-wire return loss is at minus infinity. Therefore, a relatively higher loss value (i.e., less negative) corresponds to a relatively larger impedance mismatch. In Fig. 6, solid squares correspond to the interface circuit without an IWC. The effect of the blocking capacitor (e.g., blocking capacitor **28**) in the upper POTS band is seen as a relative increase of the loss and, therefore, impedance mismatch with frequency increase. Empty squares in Fig. 6 correspond to the interface circuit with an IWC. As can be seen in the frequency range of 1 to 3 kHz, incorporation of the IWC results in about 4-dB to about 9.5-dB reduction of the two-wire return loss and, thus, improves conformance of the synthesized impedance to the Telcordia standard.

While this invention has been described with reference to illustrative embodiments, this description is not intended to be construed in a limiting sense. Various modifications of the described embodiments, as well as other embodiments of the invention, which are apparent to persons skilled in the art to which the invention pertains are deemed to lie within the principle and scope of the invention as expressed in the following claims. Although the present invention has been described with reference to particular CODEC and SLIC models, it can also be used with different CODEC and SLIC models without departing from the principles set forth in this specification.

The use of figure reference labels in the claims is intended to identify one or more possible embodiments of the claimed subject matter in order to facilitate the interpretation of the claims. Such labeling is not to be construed as necessarily limiting the scope of those claims to the embodiments shown in the corresponding figures.
